Lab 05 - Polymorphism

Instructions:

- A battle card game contains two card types: creature and spell. Each card type contains a name, cost, and ability. Additionally, a creature card contains attack, defensive, mana, and life; and a spell card contains duration, user, and target. Your objective is to define several classes that form a hierarchy and override methods in a header file named 'GameCard.h'.
- 'GameCard.h' must contain a header guard.
- The classes must be defined within a namespace named 'oopl'.
- 'GameCard.h' can only include the libraries iostream, string, sstream, cctype, cmath, and iomanip.
- Each class, except for interfaces, must define all its special member functions (default constructor, copy constructor, destructor, and assignment operator). Destructors must be empty unless stated otherwise and virtual for abstract classes. The copy constructors and assignment operators must perform shallow copies.
- Each method, excluding special member functions and friends, must include pseudocode as a comment above it to receive any credit.
- Your submissions must be submitted to the GitHub repository in the Lab05 directory.
- Cheating of any kind is prohibited and will not be tolerated.
- Violating or failing to follow any of the rules above will result in an automatic zero (0) for the lab.

Grading

Task	Maximum Points	Points Earned
1	0.25	
2	0.95	
3	0.95	
4	0.95	
5	0.95	
6	0.95	
Total	5.00	

Note: solutions will be provided for tasks colored blue only.

Task 1

•	Creates	an	interface	named	Object	that	contains
---	---------	----	-----------	-------	--------	------	----------

□ a public string pure virtual constant method named toString() that takes no parameters.

 \square a friend ostream operator that takes returns a display in the same format as toString().

Task 2

• Create an abstract class named *Card* that publicly inherits *Object* and contains

□ a private string field named id.
□ a private unsigned integer field named value.
□ a public default constructor that assigns an empty string and 0 to id and value, respectively.
□ a public string constant method named name() that takes no parameters and returns id.
□ a protected void method named name() that takes a string parameter and assigns the parameter to id.
□ a public unsigned integer constant method named cost() that takes no parameters and returns value.
□ a protected void method named cost() that takes an unsigned integer parameter and assigns the parameter to value.
□ a public void pure virtual method named ability() that takes no parameters.

"n (c)"

where n and c are the values of id and value, respectively.

Task 3

• Create an abstract class named *Creature* that publicly inherits *Card* and contains

□ a public overridden toString() method that returns a string in the format

 \square a private unsigned integer array field named aspects with a size of 5.

 \square a public default constructor that assigns 0 to each element of aspects.

 \Box a public unsigned integer constant method named attack() that takes no parameters and returns first element of aspects.

 \Box a protected void method named attack() that takes an unsigned integer parameter and assigns the parameter to the first element of aspects.

 \Box a public unsigned integer constant method named defense() that takes no parameters and returns second element of aspects.

 \Box a protected void method named defense() that takes an unsigned integer parameter and assigns the parameter to the second element of aspects.

□ a public unsigned integer constant method named mana() that takes no parameters and returns third element of aspects.

□ a protected void method named mana() that takes an unsigned integer parameter and assigns the parameter to the third element of aspects.

□ a public unsigned integer constant method named life() that takes no parameters and returns fourth element of aspects.

 \Box a protected void method named life() that takes an unsigned integer parameter and assigns the parameter to the fourth element of *aspects*.

□ a public unsigned integer constant method named damage() that takes no parameters and returns fifth element of aspects.

□ a public void method named damage() that takes an unsigned integer parameter and assigns the parameter to the fifth element of aspects only if it does not exceed the value of the fourth element of aspects.

 \square a public overridden toString() method that returns a string in the format

"n (c) LP: l] [m\nATK: a/DEF: d"

where n is id, c is value, l is the forth minus the fifth elements of aspects, m is the third element of aspects, a is the first element of aspects, and a is the second element of aspects.

$Task \ 4$

ullet Create an abstract class named $Spell$ that publicly inherits $Card$ and contains
\Box a private <i>Creature</i> pointer array field named <i>sources</i> with a size of 2.
\Box a private unsigned integer array field named <i>lengths</i> with a size of 2.
\Box a public default constructor that assigns null to each element of <i>sources</i> and 0 to each element of <i>lengths</i> .
\Box a public void virtual method named user() that takes a <i>Creature</i> pointer parameter and assigns the parameter to the first element of <i>sources</i> .
\Box a public void virtual method named target() that takes a <i>Creature</i> pointer parameter and assigns the parameter to the second element of <i>sources</i> .
\Box a public unsigned integer constant method named uses() that takes no parameters and returns second element of lengths.
\Box a protected void method named uses() that takes an unsigned integer parameter and assigns the parameter to the second element of <i>lengths</i> only if does not exceed the first element of <i>lengths</i> .
\Box a public unsigned integer constant method named duration() that takes no parameters and returns first element of lengths.
\Box a protected void method named duration() that takes an unsigned integer parameter and assigns the parameter to the first element of $lengths$.
Task 5
• Create a class named <i>Warrior</i> that publicly inherits <i>Creature</i> and contains
\Box a private unsigned integer field named boost.
\Box a private Boolean field named <i>active</i> .
\Box a public default constructor that uses the default $Creature$ values, assigns 0 to $boost$ and false to $active$.
\Box a public overloaded constructor that takes a string parameter and six unsigned integer parameters, respectively. It assigns the string parameter to id , the integer parameters to $value$, the first four elements of $aspects$, and $boost$, respectively, 0 to the fifth element of $aspects$, and false to $active$
□ a public overridden ability() method. If active is false and the fifth element of aspects is greater than 0, it adds boost to the first element of aspects and assigns true to active. And if the fifth element of aspects is zero and active is true, it removes boost from the first element of aspects and assigns false to active.
Task 6
ullet Create a class named $Restoration$ that publicly inherits $Spell$ and contains
\Box a private unsigned integer field named <i>restore</i> .
\Box a public default constructor that uses the default <u>Spell</u> values and assigns 0 to <u>restore</u> .
\Box a public overloaded constructor that takes a string parameter and three unsigned integer parameters, respectively. It assigns the string parameter to id , the integer parameters to $value$, the first element of $lengths$, and $restore$, respectively, and 0 to the second element of $lengths$.
\square a public overridden user() that assigns the parameter to all elements of <i>sources</i> .
\square a public overridden target() that assigns the parameter to all elements of sources.
□ a public overridden ability() method. If the first element of <i>sources</i> is not null and the elements of <i>lengths</i> are not equal, it reduces the fifth element of <i>aspects</i> of the first element of <i>sources</i> by <i>restore</i> and increments the second element of <i>lengths</i> by 1. If the elements of <i>lengths</i> become equal, assign null to the elements of <i>sources</i> and 0 to the second element of <i>lengths</i> .
